A model for correlations in stock markets

Noh ansatz (2000)

A market is composed of several groups, within which the stock price fluctuations are correlated. This connects the spectral properties or price fluctuations and the structure of correlations:

$$X_i = g_{s_i} \eta_{s_i} + \sqrt{1 - g_{s_i}} \epsilon_i.$$

- 1 s_i denotes the cluster to which the i -th object belongs, given feature X_i
- 2 η_{s_i} denotes the **synchronous variation** of the cluster s_i
- 3 ϵ_i denotes the **random noisy part** of the features of object i
- 4 g_{s_i} denotes the similarity of objects within cluster s_i
- 5 $g_s = 1$ if all objects are identical and $g_s = 0$ if all objects are different.

Correlations and Emergence

Giada-Marsili log-likelihood function (2001)

$\{\mathcal{G}, \mathcal{S}\}$ denotes the parametrization $(\{g_s\}, \{s_i\})$ and the model assumes η_s and ϵ_i are zero-mean, unit variance processes. The probability density $P(X_i|\mathcal{G}, \mathcal{S})$ of observing the data X_i can be computed and from this, the likelihood of the parameters given the data: $P(\mathcal{G}, \mathcal{S}|X_i)$ can be deduced. This probability is only dependent on the **Pearson correlation** ρ_{ij} with the resulting likelihood function:

$$\mathcal{L}_c(\mathcal{S}) = \frac{1}{2} \sum_{s, n_s > 1} \left[\log \frac{n_s}{c_s} + (n_s - 1) \log \frac{n_s^2 - n_s}{n_s^2 - c_s} \right],$$

where n_s is the number of objects in cluster s and c_s is internal correlation of the s^{th} cluster,

$$c_s = \sum_{i=1, j=1}^N \rho_{ij} \delta_{s_i, s} \delta_{s_j, s}.$$

$\mathcal{L}_c(\mathcal{S})$ is maximal when

$$g_s^* = \sqrt{\frac{c_s - n_s}{n_s^2 - n_s}}.$$

The recursive merging algorithm

- 1 Begin with N clusters composed of singletons (for any s , $n_s = 1$).
- 2 At each step, merge the 2 clusters which result in the cost function \mathcal{L}_c of the configuration \mathcal{S} being minimised
- 3 Repeat step 2 until the single-cluster configuration is reached.

Simulating annealing approach

- 1 Sweep the lattice, generating new configurations by small random permutations of clusters
- 2 Accept a new cluster configuration (merge clusters) using Metropolis conditions
- 3 Repeat steps 1 and 2, decreasing 'temperature' in the Metropolis conditions, until likelihood is maximized

[KGV 1983, RGF 1990, GM 2001]

Novel genetic algorithm approach for \mathcal{L}_c

Each configuration is represented by a chromosome. The genes are the integer valued cluster indices and the genome length is the number of objects. The mutation rate is scaled by the current generation relative to the terminating generation.

- 1 *Mutation*: The number of clusters is randomly changed and objects are randomly re-assigned to new feasible clusters.
- 2 *Cross-over*: For a fixed number of clusters, generate random but feasible cross-overs.
- 3 Iterate 1 and 2 until fitness function reaches the convergence criterion or the terminating generation is reached.

Remarks: Implemented using a modification of the Matlab GA Toolbox.

After the dot-com bubble

America's current economic woes - from the collapse in share prices to the surge in bankruptcies - can be traced back to the biggest credit boom in its financial history... Without easy credit the stockmarket bubble could not have been sustained for so long, nor would its bursting have had such serious consequences. And unless central bankers learn their lesson, it will happen again. **Economist Sept 2002**

 - Money supply

Johannesburg Stock Exchange

- Started trading in 1887, electronic trading and settlement since 1997.
- 18th Largest stock exchange with a capitalisation of R4.9 trillion (450 billion Euro)
- 405 Listed companies (cf. 3008 listed on LSE) and 1600 listed securities.
- 10 Largest companies constitute 60% of JSE.
- Resource stocks constitute 50% of stocks by market capitalization.
- 4 Big banks in SA (excl. SARB)
- SA has GDP of 277 Billion Euros, ranked 32 (2008, www.imf.org.za)

Is $B^3 E^2$ the South African subprime?

South African Market Regulations

- Exchange Control Regulations, 1961, amended 1999, Currency and Exchanges Act, 1933
- The Financial Intelligence Act, 2001 (FICA) [*know you client*]
- The Financial Advisory and Intermediary Services Act, 2002 (FAIS) [*know you banker*]

 - Money supply

Observations

- Markets coagulated on important event days.
- JSE often lagged the LSE.
- Periods of fragmentation quickly follow after coagulation.
- JSE has more larger groups, the LSE had more smaller groups.

JSE Market structure from correlations

Minimal Spanning Tree (MST)

Data: Top 40 of JSE and Top 100 of LSE by market capitalization,
1 Jan 09 - 1 Jan 09

Four movies using an exponentially weighted moving average to
estimate the covariance:

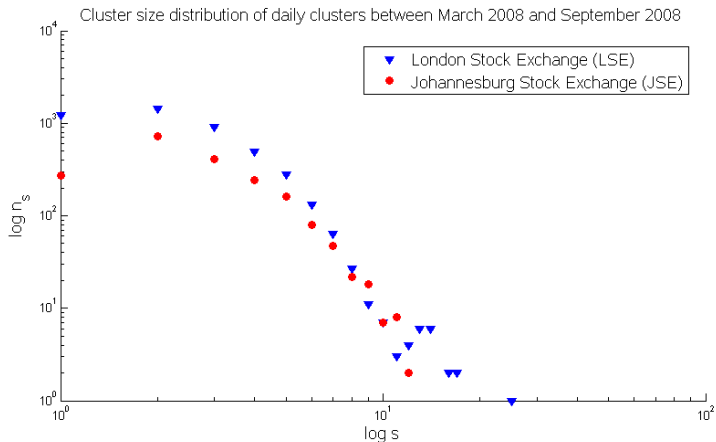

- JSE_D_LJSEOVER_SPIN_MARKET.avi
- JSE_D_LJSEOVER_SPIN_NOMARKET.avi
- LSE_D_LTOTMKUK_SPIN_MARKET.avi
- LSE_D_LTOTMKUK_SPIN_NOMARKET.avi

Possible explanations

- Macroeconomic sector effects may explain larger groups on the JSE.
- Pairs-trading is relatively more profitable on the JSE than LSE - this may be linked to an explanation for the dominance of smaller groups on the LSE.
- Any hedging or risk management strategy based on economic sectors would have been problematic.

Ex-market Mode Clustering on LSE & JSE

Outline

Securities Industry and Financial Markets Association (SIFMA)

col2: Includes GNMA, FNMA, and FHLMC mortgage-backed securities and CMOs, and CMBS, and private-label MBS/CMOs

US Money Supply

M1: assets that strictly conform to the definition of money: assets that can be used to pay for a good or service or to repay debt.

M2: M1 + savings deposits, time deposits less than \$100,000 and money market deposit accounts for individuals.

M3: M2 + large time deposits, institutional money-market funds, short-term repurchase agreements, along with other larger liquid assets.

Figure: Wikipedia, see also <http://www.federalreserve.gov>

US Debt

2008 GDP (in million USD):

Global	USA	SA
60,689,812	14,624,660	277 (ranked 32)

Some 2008 figures:

- US Consumers spend 130% of income
- US current account deficit rises to 7% of GPP (800 billion USD)
- US Gov debt as percentage of GDP betw 61% & 73% (10.7 trillion USD)
 - excl. Fannie Mae and Freddie Mac (MBS debt 8.9 trillion USD)
 - more than 25% of this is foreign held (mostly China and Japan)

Source: www.imf.org

see also: <http://www.federalreserve.gov> [USA]

Summary

- Clustering was present but not stable.
- There was a drop in the number of small clusters, particularly on the JSE.

Further questions:

- Can we learn more about what the market agents were doing?
- Does the analysis tell us anything interesting for risk management?
